

## Solutions

1. Consider the dilation carrying  $\omega$  to the excircle opposite to  $A$ . Point  $E$  is mapped to  $F$ , which must also be the point of tangency of the excircle to  $BC$ .

2. Let the excircle  $\Omega$  be tangent to  $BC$  at  $F$ , and  $G$  a point such that  $FG$  is diameter of  $\Omega$ . Let  $\omega$  be the incircle of  $\triangle ABC$ . Then the homothety with centre  $A$  carrying  $\omega$  to  $\Omega$  maps  $E$  to  $G$ , so  $A, E, G$  are collinear. Hence  $E$  is the intersection of  $AG$  and  $DF$ . Therefore  $E$  lies on the line connecting the midpoints of  $AG, DF$  which is  $MI_a$ .

3. The dilation with centre  $P$  carrying  $\omega$  to  $\Gamma$  sends  $K$  to a point  $M$  on arc  $AB$  not containing  $P$ . Line  $AB$  is sent to a line  $l$  parallel to  $AB$  and tangent to  $\Gamma$  at  $M$ . Angle-chasing finishes the problem.

4. (Proof from Yufei Zhao's notes on Lemmas in Euclidian Geometry). Extend  $KE$  to meet  $\Gamma$  at  $M$ .  $M$  is the midpoint of arc  $BC$  (see problem 3) hence  $A, I, M$  are collinear. Let  $EI$  intersect  $\omega$  at  $F'$ . We will show  $AF'$  is tangent to  $\omega$ .

Since  $\angle EF'K, \angle MAK$  subtend arcs  $EK, MK$  in circles  $\omega, \Gamma$  and  $MK$  is the image of  $KE$  under the homothety carrying  $\omega$  onto  $\Gamma$  it follows that  $\angle EF'K = \angle MAK$  so  $A, K, I, F'$  are concyclic.

Since  $\angle BCM = \angle CBM = \angle CKM$  it follows that  $\triangle MEC \sim \triangle MCK$  hence  $MI^2 = MC^2 = ME \cdot MK$ , so  $MI$  is tangent to the circumcircle of  $\triangle KIM$ . Hence  $\angle AF'K = \angle AIK = \angle IEK$  so  $AF'$  is tangent to  $\omega$  and  $F \equiv F'$ .

5. Notice that  $\angle O_1DO_2 = 90^\circ$ . Let  $\omega_1$  be tangent to  $AD, DC$  at  $F, E$  and  $\omega_2$  be tangent to  $AD, BD$  at  $H, G$ . Then  $GH, FE$  intersect at  $I$ . The rest is a simple trig bash.

6. Let  $T$  be the insimilicentre of  $\omega$  and  $\Gamma$ . By the Monge-d'Alembert Theorem  $A', D, T$  are collinear. Hence  $A'D, B'E, C'F$  intersect at  $T$ .

7.  $B'C'$  and  $BC$  intersect at  $N$ ; they are polars of  $A, A'$  respectively. Hence  $AA'$  is the polar of  $N$ . [This is a useful fact!] Similarly  $BB'$  is the polar of  $M$ . Hence  $MN$  is the polar of  $N$ . The result follows.

8. Let  $\omega$  be tangent to  $BC$  at  $D$ .  $AD$  intersect  $PQ, \omega$  at  $K, S$ . Considering the dilation carrying the incircle of  $\triangle APQ$  to  $\omega$  it follows that  $PK = RQ$  and  $MK = MR$ . Also  $\angle RSK = 90^\circ$  hence  $MR = MK = MS$  and  $MS$  is tangent to  $\omega$ .  $AD$  is the polar of  $T$  with respect to  $\omega$  hence  $TS$  is tangent to  $\omega$ . The result follows.

9. Let  $BI$  intersect  $EF$  at  $X'$ ,  $EF$  intersect  $BC$  at  $T$ , and  $D$  be the point of tangency of  $\omega$  with  $BC$ . Then  $(T, D; B, C)$  is harmonic and  $XB$  is the angle bisector of  $\angle FX'D$  hence  $X'C \perp BX$ . Hence  $X \equiv X'$  and  $X, Y$  lie on  $EF$ .

Let  $ID$  intersect  $EF$  at  $N'$ . Let  $P, Q$  be points on  $AB, AC$  so that  $N$  lies on  $PQ$  and  $PQ \parallel BC$ . The projections of  $I$  onto  $AF, EE, FE$  are collinear, so by Simpson's theorem  $I, P, A, Q$  are concyclic. Since  $\angle PAI = \angle QAI$  it follows that  $IP = IQ$  and  $N'P = N'Q$  hence  $A, N', M$  are collinear and  $N' \equiv N$ . So  $N$  lies on  $ID$ .

By angle chasing  $I$  is the incentre of  $\triangle YXD$  and  $\triangle DXY \sim \triangle ABC$ . Since  $DN$  is the angle bisector of  $\angle YDX$  (as it contains  $I$  it follows that  $\frac{NX}{NY} = \frac{DX}{DY} = \frac{AC}{AB}$ ).

10. Let  $U, V, W$  be centers  $\omega_a, \omega_b, \omega_c$  respectively. Let  $R$  be the intersection of  $EF, VW$ ;  $S$  the intersection of  $ED, VW$ ,  $T$  the intersection of  $FD, UV$ . (Some of these might be points of infinity but that's ok). Then  $R, S, T$  are the exsimilicentres between pairs of the three circles. Hence  $R$

lies on  $BC$ ,  $S$  lies on  $AC$ ,  $T$  lies on  $AB$  (as they are common external tangents between the pairs of circles). By Monge's Theorem  $R, S, T$  are collinear, hence  $\triangle ABC, \triangle DEF$  are perspective with respect to a line. By Desargues' theorem these triangles are perspective with respect to a point. The result follows.

**11.** Let  $\Gamma, \omega_1(O_1), \omega_2(O_2), \omega_3(O_3), \omega_4(O_4)$  be the circumcircles of the  $ABCD, \triangle APB, \triangle BPC, \triangle CPD, \triangle DPA$ , respectively ( $\omega(O_1)$  means circle  $\omega_1$  with centre  $O_1$ ). Let  $\omega_1 \cap \omega_3 = P, N$  and  $\omega_2 \cap \omega_4 = P, M$ . Then  $I$ , the point of intersection of  $O_1O_3$  and  $O_2O_4$  lies on the perpendicular bisectors of  $PM, PN$  hence is the centre of the circumcircle  $\zeta$  of  $\triangle PNM$ . Let  $AD \cap BC = F, AB \cap CD = G$ . Then  $OE \perp FG$  by Brocard's Theorem, and it suffices to show  $OI \perp FG$  (as then  $O, I, E$  are collinear). By the radical axis theorem,  $PM, AD, BC$  are concurrent at  $F$  and  $PN, AB, CD$  are concurrent at  $G$ . Since  $F$  lies on the radical axes of circles  $\zeta, \omega_3$  and  $\omega_3, \Gamma$  it follows that  $F$  lies on the radical axis of  $\omega_3, \Gamma$ . Similarly  $G$  lies on the radical axis of  $\omega_3, \Gamma$ . So  $OE \perp FG$  and the result follows.

**12.** By Thebault's theorem  $O_1, I, O_2$  are collinear. After some angle chasing we get  $I$  is the midpoint of  $O_1O_2$ . Assume  $l$  passes through  $M$ . Then  $\angle O_1MO_2 = 90^\circ$ . Also  $\angle O_1DO_2 = 90^\circ$  hence  $O_1, D, M, O_2$  lie on a circle with centre  $I$ . Hence  $ID = IM$ . Let the sides of the triangle be  $a, b, c$  and  $F$  be the point of tangency of the incircle with  $BC$ . Then  $2BF = BD + DM$  hence  $a + c - b = c \cdot \frac{a^2 + c^2 - b^2}{2ac} + \frac{a}{2}$ . Simplifying we get  $c + b = 2a$ . **Note:** You should not be afraid of using trig bash in your solutions. However, first try to look for a purely geometric solution; use trig bash only when you know where it is going (and not just thoughtless length calculations).

**13.** Let  $\{K\} \equiv CI \cap FE, \{G\} \equiv BI \cap EF$ . Then  $BK \perp CK$  and  $BG \perp CG$ . Hence  $\{H\} \equiv BK \cap CG$ . Let  $J$  be the midpoint of  $EF$ . Let  $P'$  be the intersection by  $HJ$  and  $DM$ . It suffices to prove that  $P'$  is the midpoint of  $DM$ .

Let  $S$  be the projection of  $H$  onto  $EF$  and  $Y$  the intersection of  $HD$  and  $EF$ . Since  $MD \parallel HS$ , in order to prove  $P$  is the midpoint of  $DM$ , it suffices to prove the pencil  $H(M, J, Y, S)$  is harmonic, i.e. that  $(M, Y'J, S)$  is harmonic. Since  $MD \parallel JI \parallel HS$ , considering the pencil  $P_\infty(M, J, Y, S)$  and intersecting it with  $HD$  (where  $P_\infty$  is the intersection of  $MD$  and  $HS$ ) it suffices to prove  $(D, Y; I, H)$  is harmonic.

Since  $BG, CH$  and  $ID$  are altitudes of  $\triangle BIC$  it follows that  $EI$  is the angle bisector of  $\angle KGD$ . Since  $\angle HEI = 90^\circ$  it follows that  $(D, Y; I, H)$  is harmonic and the result follows.

**14.** Let  $\Gamma(O)$  be the circle tangent to the lines  $AB, BC, AD$  and let  $\omega_1, \omega_2, \omega_3$  be the incircles of triangles  $APD, BPC$  and  $CPD$  respectively.

Since  $A$  is the exsimilicenter of  $\omega_1$  and  $\Gamma$  and  $K$  is the insimilicenter of  $\omega_1$  and  $\omega_3$ , by the Monge-D'Alembert theorem, the line  $AK$  intersects the line  $OI$  at the insimilicenter of  $\Gamma$  and  $\omega_3$ . Similarly, line  $BK$  intersects  $OI$  at the same insimilicenter  $F$  of  $\Gamma$  and  $\omega_3$ . It suffices to prove that  $E$  lies on the line  $OI$ .

By properties of tangents it follows that  $AP + CD = PC + AD$  and  $BP + CD = BC + PD$  so there exist circles  $\omega_5, \omega_6$  inscribed in quadrilaterals  $APCD, BCPD$ . Let  $X$  be the exsimilicentre of  $\omega_1, \omega_3$  and  $Y$  the exsimilicentre of  $\omega_2, \omega_3$ . By Monge-D'Alembert theorem applied to circles  $\omega_1, \omega_3, \omega_5$  and to circles  $\omega_2, \omega_3, \omega_5$  it follows that  $A, C, X$  and  $B, D, Y$  are collinear. Let  $E'$  be the exsimilicentre of  $\Gamma$  and  $\omega_3$ . By the Monge's theorem applied to  $\Gamma, \omega_1, \omega_3$  it follows that  $A, X, E'$  are collinear. So  $E'$  lies on  $AC$  and on  $OI$ . Similarly  $E'$  lies on  $BD$  and  $OI$ . Hence  $E' \equiv F$  and  $E, O, I$  are collinear.

**15.** [Proof by Ivan on AOPS] Let  $AB, CD$  meet at  $X$ ,  $AD, BC$  meet at  $Y$ , let  $k$  meet  $AB, DC, AD, BC$  at  $P, Q, R, S$  respectively. Using the tangency properties with respect to  $k$  we get:

$$BA + AD = BA + AR - DR = BP - DR = BS - DQ = BC + CQ - DQ = BC + CD$$

Let  $k_1, k_2$  meet  $AC$  at  $J, L$  respectively. Then  $AB + JC = BC + AJ$  and  $DA + LC = DC + LA$ . Adding and using  $BA + AD = BC + CD$  we get  $JC + LC = AL + AJ$  hence  $AL = JC$ .

Let the excircle of  $\triangle ABC$  on the side  $AC$  be  $k_3$ , and the excircle of  $\triangle ADC$  on the side  $AC$  be  $k_4$ . Then  $k_3, k_4$  meet  $AC$  at  $L$  and  $J$ .

Construct the tangent of  $k$  which is parallel to  $AC$  (and on the same side of  $k$  as  $AC$ ). Let that tangent meet  $k$  at  $Z$ . The dilation about  $B$  takes  $k_3$  to  $k$  and  $L$  to  $Z$ . The negative dilation about  $D$  takes  $k_4$  to  $k$  and  $J$  to  $Z$ . Hence  $BL$  and  $DJ$  meet at  $Z$ .

Construct the two missing tangents to  $k_1$  and  $k_2$  which are parallel to  $AC$ , let the points of tangency be  $M$  and  $N$  respectively. Similar dilation arguments show that  $B, M, L, Z$  are collinear and  $D, N, J, Z$  are also collinear.

Since  $JM$  and  $LN$  are parallel and are diameters of  $k_1$  and  $k_2$ , then they meet at the centre of dilation which takes  $k_1$  to  $k_2$ , which we know is the point  $Z$ . Hence  $Z$  is the intersection of the common external tangents of  $k_1, k_2$ .

**16.** Let  $\Gamma$  be the circumcircle of  $\triangle ABC$ . Let  $\omega_1$  intersect  $\Gamma$  at  $B, D$  and  $DC$  at  $D, E$ . Then  $\angle XED = 180^\circ - \angle XBD = \angle ACK$  so  $XE \parallel AC$ . Simple angle chasing gives  $\angle AXY = \angle AYX$ ; let  $\angle AXY = \alpha$ . Then  $\angle YXE = \alpha$ ,  $XY$  is tangent to  $\omega_1$  at  $X$  so  $\angle XKC = \alpha$  and  $XYCD$  is cyclic. By the radical axis theorem applied to  $\Gamma$  and the circumcircles of  $\triangle AXY$  and  $XYCD$  it follows that  $AQ, XY, CD$  are concurrent at a point  $O$ . Since  $XE \parallel YC$  and  $XY$  is tangent to  $\omega_1, \omega_2$  then the homothety with centre  $O'$  taking  $\omega_1$  to  $\omega_2$  takes  $X$  to  $Y$  and  $E$  to  $C$ , where  $O'$  is the exsimilicentre of  $\omega_1, \omega_2$ . Since  $XY \cap EC = O$  it follows that  $O$  is the exsimilicentre of  $\omega_1, \omega_2$ .

Simple angle chasing gives the circumcircle  $\zeta$  of  $\triangle XYK$  is tangent to  $OK$  at  $K$ . Since  $\angle XKP = \angle PXY, \angle YKP = \angle XYP$  it follows that  $\angle XKY = \angle XYP + \angle PXY = \angle XYB = \angle AXY$  so  $AB$  is tangent to  $\zeta$  at  $X$ . Similarly  $AC$  is tangent to  $\zeta$  at  $Y$ . Hence  $KA$  is the polar of  $O$  with respect to  $\zeta$  (since  $XY, CD$  are polars of  $K, A$  and intersect at  $O$ ). Let  $KA$  intersect  $\zeta$  at  $K, R$  and  $XY$  at  $S$ . Then  $(O, S; X, Y)$  is harmonic (proved in previous problems) and if  $M$  is the midpoint of  $XY$  then  $OR^2 = OK^2 = OQ \cdot OA = OX \cdot OY$  (power of a point) =  $OS \cdot OM$  (property of harmonic division).

Consider the inversion with centre  $O$  that fixes points  $R, K$ . The line  $AK$  is carried to a circle passing through  $R, K, O$  and if this circle intersects  $OA, OS$  at  $Q', M'$  respectively then  $OR^2 = OK^2 = OQ' \cdot OA = OS \cdot OM'$ . Hence  $Q \equiv Q'$  and  $M \equiv M'$  and  $OQRMK$  is cyclic. Also  $K, P, M$  are collinear (as  $M$  lies on the radical axis of  $\omega_1, \omega_2$ ). Hence  $\angle QKP = \angle QKM = \angle QOY$ . Since  $AY^2 = AR \cdot AK = AQ \cdot AO$  it follows the circumcircle of  $\triangle OQY$  is tangent to  $AC$  and  $\angle QKP = \angle QOY = \angle QYA = \angle QXA$  and we are done.
